# Lab 3: Simple Steganography

## Brian Hosler & Sarah Peachey February 19, 2018

#### Abstract

Being able to hide information into images can be useful for several reasons. If you want to determine if an image has been edited or compressed, Least Significant Bit Hiding can be a technique for implementing soft watermarking. But someone could easily remove the LSB plane, edit the image, and then put the LSB plane back in. So more advanced algorithms like Yeung-Mintzer Watermarking are used where a user must know the random seed in order to extract the watermark. Therefore, it is more secure.

<b>2</b>	Yeung-Mintzer Watermarking	5

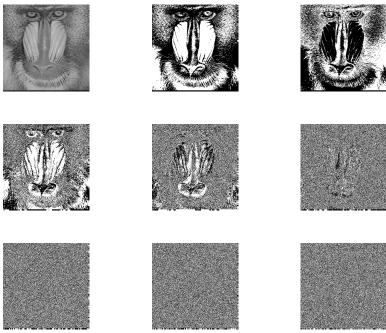

### 1 Least Significant Bit Data Hiding

Least significant bit hiding is when you take the MSB of the payload and place it into the LSB of the host image. The below code executes a function that examines one bit plane of an image, for every image.

```
pep=imread('Assingment_3_Files/peppers.tif');
bab=imread('Assingment_3_Files/baboon.tif');
figure
\mathbf{subplot}(3,3,1)
imshow (pep)
for i=1:8
    subplot (3,3,10-i)
    imshow(getBP(pep,i))
end
                                                                         10
figure
subplot (3, 3, 1)
                                                                         12
imshow (bab)
                                                                         13
for i = 1:8
                                                                         14
    subplot (3,3,10-i)
                                                                         15
    imshow(getBP(bab, i))
                                                                         16
end
```

The eight bit planes of the peppers.tif image and the baboon.tif image, are shown below. As seen the MSB plane contains what appears to be a binary version of the image, whereas the LSB plane contains what looks like noise. All the bit planes in between transition from a recognizable image to noise. The peppers.tif image becomes too noisy to recognize on bit plane 4, whereas the baboon.tif has more high frequency content and becomes too noisy on bit plane 5. The bit planes of the babbon.tif image are more noisy because the high frequency content means the bits change more often.

The following code examines the different bit planes of several images to see if there is any hidden content. As seen in the images, bit plane 2 was a watermark in the first image, and bit plane 1 was a watermark in the last two images. Then a function was written to replace the N least significant bit planes from the one image with the N most significant bit planes from another image. The top N layers of of Barabara.bmp are hidden in the peppers.tif and baboon.tif images. The peppers image becomes distorted when N=5, Barbara can be seen, and the peppers look choppy.

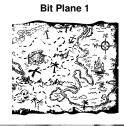

```
wmkl=imread('Assingment 3 Files/LSBwmk1.tiff');%2
wmk2=imread('Assingment 3 Files/LSBwmk2.tiff');%1
wmk3=imread('Assingment 3 Files/LSBwmk3.tiff');%1
figure
subplot(2,3,1); imshow(wmk1); title('Original')
subplot(2,3,4); imshow(getBP(wmk1,2)); title('Bit Plane 2')
subplot(2,3,2); imshow(wmk2); title('Original')
subplot(2,3,5); imshow(getBP(wmk2,1)); title('Bit Plane 1')
subplot(2,3,3); imshow(wmk3); title('Original')
                                                                  10
subplot(2,3,6); imshow(getBP(wmk3,1)); title('Bit Plane 1')
                                                                  11
barb=imread('Assingment 3 Files/Barbara.bmp');
                                                                  13
                                                                  14
imshow (BPstitch (pep, barb, 5))
                                                                  15
                                                                  16
type('getBP.m');
                                                                  17
type('BPstitch.m');
```

Original

This is the function used to get a bit plane from an image.

```
function [bp] = getBP(img, ind)
    bp=255*bitget(img, ind);
end
```

This is the function was used to replace the N least significant bits of the host image with those of the payload image.

```
\begin{array}{ll} \textbf{function} & [\operatorname{encoded}] = \operatorname{BPstitch}(\operatorname{img},\operatorname{msg},N) \\ & \operatorname{encoded} = \operatorname{uint8}(\operatorname{\textbf{zeros}}(\operatorname{\textbf{size}}(\operatorname{img}))); \\ & \textbf{for} & \operatorname{i} = (N+1) : 8 \\ & \operatorname{encoded} = \operatorname{encoded} + (2^{(i-1)}) * \operatorname{bitget}(\operatorname{img},\operatorname{i}); \end{array}
```

```
\begin{array}{c} \textbf{end} & \textbf{if N}\!\!=\!\!1 & \textbf{6} \\ & \textbf{encoded}\!\!=\!\!\textbf{encoded}\!\!+\!\textbf{bitget}\left(\text{msg},8\right); & \textbf{7} \\ & \textbf{else} & \textbf{8} \\ & \textbf{for i}\!\!=\!\!1\text{:N} & \textbf{9} \\ & \textbf{encoded}\!\!=\!\!\textbf{encoded}\!\!+\!\!\left(2^{\hat{}}\!\left(N\!\!-\!i\right)\right)\!*\!\,\textbf{bitget}\left(\text{msg},9\!-\!i\right); & \textbf{10} \\ & \textbf{end} & \textbf{11} \\ & \textbf{end} & \textbf{12} \\ & \textbf{encoded}\!\!=\!\!\textbf{uint8}\!\left(\textbf{encoded}\right); & \textbf{14} \\ & \textbf{end} & \textbf{15} \end{array}
```

### 2 Yeung-Mintzer Watermarking

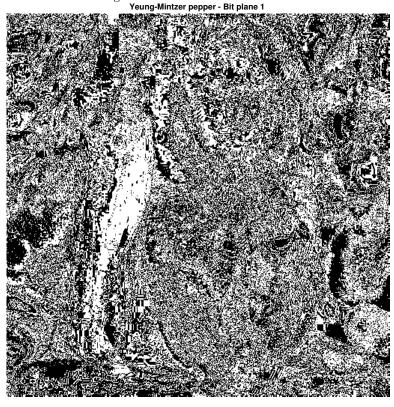

In this section, Yeung-Mintzer watermarking was implemented and tested on several different images. The strengths and weaknesses compared to LSB embedding were compared.

```
key = 256;
\text{wmk=getBP}(\text{barb}, 8) > 128;
                                                                       2
img1=pep;
[marked1] = YMwatermark( img1, wmk, key );
img2=bab;
[marked2] = YMwatermark( img2, wmk, key );
% see the LSB of marked image
                                                                       10
figure
                                                                       11
imshow(getBP(marked1,1))
                                                                       12
hold on

YM watermarking resulted in a lower signal to noise ratio than the LSB embedding. LSB embedding is guarenteed to change, at most, just the least signifigant bit. YM watermarking however will result in an indeterminate number of bit changes due to the random nature of the lookup table. The signal to noise ratio of the LSB embedding was consistently 3 dB higher than the YM embedding. To verify the functionality of the Yueng-Mintzer decoder, an image was decoded using the key 435, to reveal a tiled version of the Drexel logo as the watermark.

lsb\_psnr\_bab =

51.1391

Next, LSB and YM watermarking were compared in terms of their fragility. After detecting the watermark in the image with LSB watermarking, it is easy to modify the image and replace the least significant bits with the original watermark after. The YM watermark is harder to detect, and unless the key to the lookup table is used, it is not possible to recreate the watermark after editing the image.
